

Why I need a pair of ski boots fit for my feet ?

Everybody think that skiboot is just a kind of shoes wear on the foot for skiing and they thought the way to think a pair of shoes size they use to wear is correct. And it isn't, the major difference between skiboos and other foot shoes is the flexion of the metatarsal and phalanges. Most of the shoes are involves in walking posture which means you need a flexion between the toes and the forefoot to keep on walking. But skiboot would not allow for you to have such flexion movement as you don't need it.

The major mission of the skiboot to is read your foot information and transmit to the skis, it's like a bridge and a communicator between your feet and the skis. So it must fit your foot without further room inside the chamber where usual shoes do have room because of walking but ski boot definitely do not required for this option.

Thus when choosing a pair of skiboos, it must be measure from toe tip to heel ends and the width of the forefoot it defines whether you need extra 0.5 of size or not as it needs to control the skis steering. The boot shell was made of plastic in order to have sufficient power to apply force to control, the shell would not be comfortable for your feet as it was stiff, it needs to add a soft liner boot inside the shell to keep your foot in comfort.
